

# A Ten-Sided Shape Is Growing in Saturn's Clouds

Hubble is helping scientists watch a new wind pattern form near the ringed planet's south pole.

Saturn appears in space with its rings and a subtle ten-sided cloud pattern near one pole.

**N**ASA's Hubble Space Telescope has spotted a strange shape around Saturn's south pole. It looks like a **decagon**, a shape with ten sides. According to reporting by Live Science, scientists think the **pattern** began forming in 2023 and is getting stronger.

Saturn is the giant **planet** with bright rings. No one could stand on it like a playground. It is a gas giant, which means it is mostly made of gases. Its **weather** happens in thick layers of **clouds** and wind. From far away, those winds can make patterns big enough for telescopes to see.

The new shape is an atmospheric **wave**. That means air is moving in a repeating pattern, a little like ripples in water. It sits inside a jet stream, which is a fast river of wind. On Earth, jet streams help move storms. On Saturn, they can circle the planet for a very long time.

This discovery matters because Saturn already has one famous puzzle. At its north pole, scientists have watched a six-sided shape, called a **hexagon**, for more than 40 years. Now they may be watching a ten-sided pattern grow at the other end of the planet. That is rare. Usually, scientists see a finished pattern and wonder how it started.

Right now, Saturn's south pole is turned toward Earth enough for a good look. Saturn takes about 29 Earth years to go around the sun. As it moves, we get better views of different parts of the planet.

Hubble was not the first telescope to notice something odd. Observatories on the ground saw a wavy band near Saturn's south pole in 2024. More images in 2025 showed the band becoming more like a decagon. Hubble can see more clearly because it is above Earth's air. Earth's air can blur telescope pictures, even on a clear night.

Scientists still do not know why the shape formed now. NASA's Cassini spacecraft orbited Saturn from 2004 to 2017. It did not see this pattern. That makes researchers think the decagon is new, at least in recent Saturn history.

More observations are planned with Hubble and the James Webb Space Telescope. Scientists will compare pictures over time. If the shape grows, fades, or changes sides, each clue can teach them how giant planets move air. It may also help them understand why worlds can have weather that looks almost like geometry.

## THINK IT THROUGH

1. If you could choose what a space telescope studies next, would you keep watching Saturn or look for something new? Defend your choice.

**A strong answer:** A strong answer weighs the value of long-term evidence against the chance of finding a different discovery.

2. In what ways is Saturn's decagon like weather on Earth, and in what ways is it very different?

**A strong answer:** A strong answer compares wind patterns while noticing that Saturn is a gas giant with very different conditions.

3. Scientists do not yet know why the decagon formed now. What kind of evidence would make one explanation more convincing?

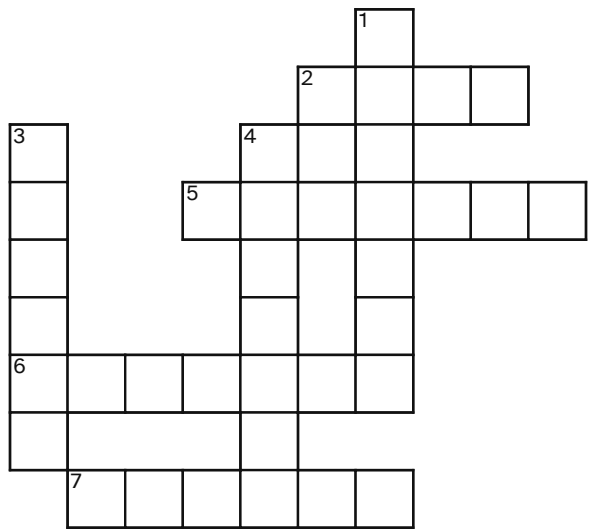

**A strong answer:** A strong answer discusses repeated observations, changes over time, and comparisons with Saturn's other pole.

### WHAT IS IN THIS PACKET

The article with a note on each question, a word search, a crossword, and the answer key to both.

### COPYING AND REUSE

Free to print, copy and hand out for classroom use. Please keep this page with the packet, so the next teacher can see where the story came from.

### More where this came from

If this short lesson worked for your class, our full workbooks go further with the same care:

- Complete units with student and teacher editions
- Worked solutions for every exercise
- Standards-aligned, classroom-tested, print-ready
