# A Fossil Shows Insects Once Had Many More Legs

Scientists rechecked an old fossil and found a clue about how insects became the six-legged animals we know.

A magnifying glass reveals a many-legged insect fossil on a dark stone slab.

According to Science News Explores, scientists rechecked a 324-million-year-old **fossil** from west Texas and found something surprising. It looked like an early **insect**, but it had 24 legs. Insects today have six. The find helps scientists picture what insects were like before ants, beetles and butterflies filled the land.

A fossil is a trace of an **ancient** living thing saved in rock. This one was found in 1985 near Big Bend National Park. For years, it sat in a **museum** drawer in San Diego. Scientists had thought it was a young crustacean, an animal from the group that includes shrimp and crabs.

Then researcher Erik Tihelka noticed a drawing of it in an old science book. He went to see the real fossil. At first, it looked like a black smudge. Then he used special light filters that cut glare. The smudge began to show a body.

The fossil had three pairs of walking legs, like insects today. It also had extra short legs along its **abdomen**, the long back part of its body. Some of those legs were shaped like **paddles**. That clue suggests the animal may have moved through muddy, **shallow** water.

The animal was named Chosha praecursor. The name was inspired by a Navajo creation story and by words meaning insect and predecessor. A predecessor is

something that came before. Scientists think Chosha sat just outside the group that includes all insects alive today. Tihelka also compared it with strange fossils from Scotland and Illinois. They seemed to fit near the same branch of the insect family tree.

That matters because insects did not simply appear as the six-legged animals we know. Over many, many generations, living things can change. That long change is called evolution. Chosha may show one step in the change from many-legged, water-loving animals to insects that lived on land.

Imagine finding this fossil in a drawer. It would not sparkle like a gem. It might look like a flat dark mark on stone. But with the right tools, that mark can become a clue. It can tell a story about Earth long before classrooms, playgrounds, or even dinosaurs. A small smudge can help explain why a ladybug has six legs today.

THINK IT THROUGH

1. **Was it a mistake for scientists to leave the fossil in a drawer for years, or was that a normal part of science?**

   > **A strong answer:** A strong answer should weigh limited time and tools against the value of saving old evidence for later study.

2. **If a museum had money for only one project, should it search for new fossils or recheck old ones? Defend your choice.**

   > **A strong answer:** A strong answer should compare the excitement of new finds with the chance that old collections hold overlooked clues.

3. **Should textbooks still say insects have six legs, even after this discovery? Why or why not?**

   > **A strong answer:** A strong answer should separate what is true for insects alive today from what fossils can show about ancient relatives.

## WHAT IS IN THIS PACKET

The article with a note on each question, a word search, a crossword, and the answer key to both.

## COPYING AND REUSE

Free to print, copy and hand out for classroom use. Please keep this page with the packet, so the next teacher can see where the story came from.

**More where this came from**

If this short lesson worked for your class, our full workbooks go further with the same care:

- Complete units with student and teacher editions
- Worked solutions for every exercise
- Standards-aligned, classroom-tested, print-ready
